	nucleosome particles by wrapping 146 base pairs of DNA in a left-handed super-helical turn
	sequentially to form chromosomal fiber. Two molecules of each of the four core histones (H2A
	H2B, H3, and H4) form the octamer, formed of two H2A-H2B dimers and two H3-H4 dimers,
	forming two nearly symmetrical halves by tertiary structure. Over 80 % of nucleosomes contain
	the linker Histone H1, derived from an intronless gene that interacts with linker DNA between
	nucleosomes and mediates compaction into higher order chromatin. Histones are subject to
	posttranslational modification by enzymes primarily on their N-terminal tails, but also in their
	globular domains. Such modifications include methylation, citrullination, acetylation,
	phosphorylation, sumoylation, ubiquitination and ADP-ribosylation.
Molecular Weight:	~30kDa
Gene ID:	3005
