| | Background: Cytochrome c oxidase (COX), the terminal enzyme of the mitochondrial respiratory |
| | chain, catalyzes the electron transfer from reduced cytochrome c to oxygen. It is a heteromeric |
| | complex consisting of 3 catalytic subunits encoded by mitochondrial genes and multiple |
| | structural subunits encoded by nuclear genes. The mitochondrially-encoded subunits function |
| | in the electron transfer and the nuclear-encoded subunits may function in the regulation and |
| | assembly of the complex. This nuclear gene encodes polypeptide 1 (liver isoform) of subunit |
| | VIa, and polypeptide 1 is found in all non-muscle tissues. Polypeptide 2 (heart/muscle isoform) |
| | of subunit VIa is encoded by a different gene, and is present only in striated muscles. These two |
| | polypeptides share 66 % amino acid sequence identity. It has been reported that there may be |
| | several pseudogenes on chromosomes 1, 6, 7q21, 7q31-32 and 12. However, only one |
| | pseudogene (COX6A1P) on chromosome 1p31.1 has been documented. [provided by RefSeq, |
