	Background: The major eukaryotic mRNA decay pathway occurs through deadenylation,	
	decapping, and 5' to 3' degradation of the mRNA. Decapping is a critical control point in this	
	decay pathway. Edc4 (enhancer of mRNA decapping 4), also known as human enhancer of	
	decapping large subunit (HEDLS), RCD-8 or Ge-1, is a 1,401 amino acid protein belonging to the	
	WD repeat EDC4 family that is involved in mRNA decapping during mRNA degradation. As part	
	of the mRNA degradation process, Edc4 becomes part of a complex that also contains hDcp1a,	
	hDcp2a, RCK and Edc3. Localizing to P-body and cytoplasm, Edc4 contains a nuclear	
	localization sequence (NLS) which enables it to selectively enter the nucleus as well. Edc4	
	becomes phosphorylated upon DNA damage and exists as two alternatively spliced isoforms	
	that are encoded by a gene that maps to human chromosome 16q22.1.
