	to intracellular effectors. Each of a very broad range of receptors specifically detects an		
	extracellular stimulus (a photon, pheromone, odorant, hormone or neurotransmitter) while the		
	effectors (i.e., adenyl cyclase), which act to generate one or more intracellular messengers, are		
	less numerous. In mammals, G protein Alpha, Beta and Gamma polypeptides are encoded by at		
	least 16, 4 and 7 genes, respectively. Most interest in G proteins has been focused on their		
	Alpha subunits, since these proteins bind and hydrolyze GTP and most obviously regulate the		
	activity of the best studied effectors. Four distinct classes of G Alpha subunits have been		
	identified, these include G Alpha s, G Alpha i, G Alpha q and G Alpha 12/13. The two members of		
	the fourth class of G Alpha subunit proteins, G Alpha 12 and G Alpha 13, are insensitive to ADP-		
	ribosylation by pertussis toxin, share 67 $\%$ identity with each other and less than 45 $\%$ identity		
	with other G Alpha subunits and are widely expressed in a broad range of tissue
