Background:	The 26S proteasome is a multicatalytic proteinase complex with a highly ordered structure composed of 2 complexes, a 20S core and a 19S regulator. The 20S core is composed of 4
	rings of 28 non-identical subunits, 2 rings are composed of 7 alpha subunits and 2 rings are
	composed of 7 beta subunits. The 19S regulator is composed of a base, which contains 6

	ATPase subunits and 2 non-ATPase subunits, and a lid, which contains up to 10 non-ATPase
	subunits. Proteasomes are distributed throughout eukaryotic cells at a high concentration and
	cleave peptides in an ATP/ubiquitin-dependent process in a non-lysosomal pathway. An
	essential function of a modified proteasome, the immunoproteasome, is the processing of
	class I MHC peptides. The immunoproteasome contains an alternate regulator, referred to as
	the 11S regulator or PA28, that replaces the 19S regulator. Three subunits (alpha, beta and
	gamma) of the 11S regulator have been identified. This gene encodes the alpha subunit of the
	11S regulator, one of the two 11S subunits that is induced by gamma-interferon. Three alpha
	and three beta subunits combine to form a heterohexameric ring. Alternative splicing results in
	multiple transcript variants.
