Background:	Background: The cluster of differentiation (CD) system is commonly used as cell markers in immunophynotyping. Different kinds of cells in the immune system can be identified through
	the surface CD molecules which associating with the immune function of the cell. There are

	more than 320 CD unique clusters and subclusters have been identified. Some of the CD
	molecules serve as receptors or ligands important to the cell through initiating a signal cascade
	which then alter the behavior of the cell. Some CD proteins do not take part in cell signal
	process but have other functions such as cell adhesion. CD83 is considered as a marker of
	mature dendritic cells as well as an adhesion receptor that binds to resting monocytes and a
	subset of activated CD8+ T cells. In certain conditions, CD83 tended to dimerize or even
	multimerize through its aberrant intermolecular disulfide bonds. The injection of CD83-Ig can
	significantly enhaunce the rate of tumor growth and inhibit the T cell growth.
