Background: TMEM166, also known as FAM176A (family with sequence similarity 176, member
A), is a 152 amino acid protein encoded by a gene mapping to human chromosome 2. The
second largest human chromosome, 2 consists of 237 million bases encoding over 1,400
genes and making up approximately 8 % of the human genome. A number of genetic diseases
are linked to genes on chromosome 2. Harlequin icthyosis, a rare and morbid skin deformity, is
associated with mutations in the ABCA12 gene. The lipid metabolic disorder sitosterolemia is
associated with ABCG5 and ABCG8. An extremely rare recessive genetic disorder, Alstr
syndrome is due to mutations in the ALMS1 gene. Interestingly, chromosome 2 contains what
appears to be a vestigial second centromere and vestigial telomeres which gives credence to
the hypothesis that human chromosome 2 is the result of an ancient fusion of two ancestral
chromosomes seen in modern form today in apes.
