|  | Background: MAX protein is a member of the basic helix-loop-helix leucine zipper (bHLHZ) |
|  | family of transcription factors. It is able to form homodimers and heterodimers with other |
|  | family members, which include Mad, Mxi1 and Myc. Myc is an oncoprotein implicated in cell |
|  | proliferation, differentiation and apoptosis. The homodimers and heterodimers compete for a |
|  | common DNA target site (the E box) and rearrangement among these dimer forms provides a |
|  | complex system of transcriptional regulation. Mutations of this gene have been reported to be |
|  | associated with hereditary pheochromocytoma. A pseudogene of this gene is located on the |
|  | long arm of chromosome 7. Alternative splicing results in multiple transcript variants. |
