| | Background: CCDC17, also known as FLJ17921 or RP4-697E16.4, is a 622 amino acid protein |
| | expressed as four isoforms and encoded by a gene mapping to human chromosome 1. |
| | Chromosome 1 is the largest human chromosome spanning about 260 million base pairs and |
| | making up 8 % of the human genome. There are about 3,000 genes on chromosome 1, and |
| | considering the great number of genes there are also a large number of diseases associated |
| | with chromosome 1. Notably, the rare aging disease Hutchinson-Gilford progeria is associated |
| | with the LMNA gene which encodes lamin A. When defective, the LMNA gene product can build |
| | up in the nucleus and cause characteristic nuclear blebs. The mechanism of rapidly enhanced |
| | aging is unclear and is a topic of continuing exploration. The MUTYH gene is located on |
| | chromosome 1 and is partially responsible for familial adenomatous polyposis. Stickler |
| | syndrome, Parkinsons, Gaucher disease and Usher syndrome are also associated with |
| | chromosome 1. A breakpoint has been identified in 1q which disrupts the DISC1 gene and is |
| | linked to schizophrenia. Aberrations in chromosome 1 are found in a variety of cancers |
| | including head and neck cancer, malignant melanoma and multiple myeloma. |
