Target Details				
Background:	Synonyms: F102B_HUMAN, Fam102b, Protein FAM102B.			
	Background: Chromosome 1 is the largest human chromosome spanning about 260 million			
	base pairs and making up 8 % of the human genome. There are about 3,000 genes on			
	chromosome 1, and considering the great number of genes there are also a large number of			
	diseases associated with chromosome 1. Notably, the rare aging disease Hutchinson-Gilford			
	progeria is associated with the LMNA gene which encodes lamin A. When defective, the LMNA			
	gene product can build up in the nucleus and cause characteristic nuclear blebs. The			
	mechanism of rapidly enhanced aging is unclear and is a topic of continuing exploration. The			
	MUTYH gene is located on chromosome 1 and is partially responsible for familial adenomatous			
	polyposis. Stickler syndrome, Parkinsons, Gaucher disease and Usher syndrome are also			
	associated with chromosome 1. A breakpoint has been identified in 1q which disrupts the			
	DISC1 gene and is linked to schizophrenia. Aberrations in chromosome 1 are found in a variety			
	of cancers including head and neck cancer, malignant melanoma and multiple myeloma. The			
	FAM102B gene product has been provisionally designated FAM102B pending further			
	characterization.
