Background:	Synonyms: GATA binding protein 5, GATA-binding factor 5, GATA5, GATA-5, GATA5_HUMAN,
	Transcription factor GATA-5.
	Background: Members of the GATA family share a conserved zinc finger DNA-binding domain
	and are capable of binding the WGATAR consensus sequence. GATA-1 is erythroid-specific and
	is responsible for the regulated transcription of erythroid genes. It is an essential component in
	the generation of the erythroid lineage. GATA-2 is expressed in embryonic brain and liver, HeLa
	and endothelial cells, as well as in erythroid cells. Studies with a modified GATA consensus
	sequence, AGATCTTA, have shown that GATA-2 and GATA-3 recognize this mutated
	consensus while GATA-1 has poor recognition of this sequence. This indicates broader
	regulatory capabilities of GATA-2 and GATA-3 than GATA-1. GATA-3 is highly expressed in T
	lymphocytes. GATA-4, GATA-5 and GATA-6 comprise a subfamily of transcription factors. Both
	GATA-4 and GATA-6 are found in heart, pancreas and ovary, lung and liver tissues exhibit GATA
	6, but not GATA-4 expression. GATA-5 expression has been observed in differentiated heart and
	gut tissues and is present throughout the course of development in the heart. Although
	expression patterns of the various GATA transcription factors may overlap, it is not yet
	apparent how the GATA factors are able to discriminate in binding their appropriate target sites
